CURRENT FRONTEND · PROPOSED BACKEND DATA

Models to support the JustShop storefront

A practical starting point for the backend contract. The current app is a frontend demo: product data is hard-coded, the bag lives in browser local storage, and account and checkout submissions do not call a server.

Suggested core models

Product

Catalog item displayed in the collection and bag.

id · name · detail / description · price · currency · image · imageAlt · color

Use an integer minor-unit amount (for example, cents) and an ISO currency code such as ZAR, rather than floating-point currency.

User

Account identity for registration and sign-in.

id · name · email · passwordHash

The frontend asks for a name, email, and password at sign-up, and email plus password at sign-in. Store only a securely hashed password; never return it from the API.

Cart

An active bag owned by a signed-in user or guest session.

id · userId or sessionId

Each cart item needs `productId` and a positive `quantity`. The frontend currently stores each item as `{ id, quantity }`.

Order

Created only when the checkout flow is connected to the backend.

id · userId / guest contact · items · delivery address · totals · status

Order items should retain product name and unit price snapshots so past orders remain accurate if catalog details later change.

Catalog examples in the current app

- **Field Day Tote** — heavy cotton canvas, moss; current display price R38.
- **The Daily Notebook** — recycled paper, soft cover; current display price R18.

These values are hard-coded in the frontend and are examples, not a persistent catalog or agreed backend pricing contract.

Checkout and delivery details

The current checkout form collects the following fields:

- **Contact:** email address, phone number
- **Recipient:** first name, last name
- **Address:** street address, optional apartment / suite
- **Locality:** suburb, city, province, postal code

For the order model, these can be grouped into a delivery-address object. The frontend supplies South African provinces and formats prices as ZAR.

Suggested ownership and behavior

Server is the source of truth

Keep product prices and availability on the server. Send product IDs and quantities from the client; calculate the authoritative subtotal and order total on the backend.

Guest and signed-in bags

Decide whether guest carts are supported and how they are associated with a session. If accounts are introduced, specify whether and how a guest bag merges after sign-in.

> **Not implemented / decisions needed:** checkout currently shows a preview only. It does not create an order, save delivery details, or process a payment. Shipping rates, taxes, payment provider, order statuses, and guest-checkout policy are not defined yet. Agree these before treating the model as final.
